Team V.P.R.H

Mechanical

Team Lead: Vinay M (20Bmn1049 )

The following is torque equations we derived based on few assumptions

#1 The exoskeleton weight is evenly distributed above the knee

# The weight of lower part of exoskeleton below the knee is half of the entire weight of exoskeleton

$$T_1 = (M \cdot L + m \cdot z') g \sin \theta + \frac{C_{\text{hip}}}{2} l_{\text{hip}}$$

$$T_2 = (M g \sin \theta + \frac{C}{4}) l_{\text{knee}}$$

M → Mass of box

m → Weight of battery

L → Horizontal distance of hip joint to box

z' → Vertical distance of hip joint to centre of battery

$l_{\text{hip}}$  → length of hip to knee

$l_{\text{knee}}$  → length of knee to ankle

C → weight of exoskeleton

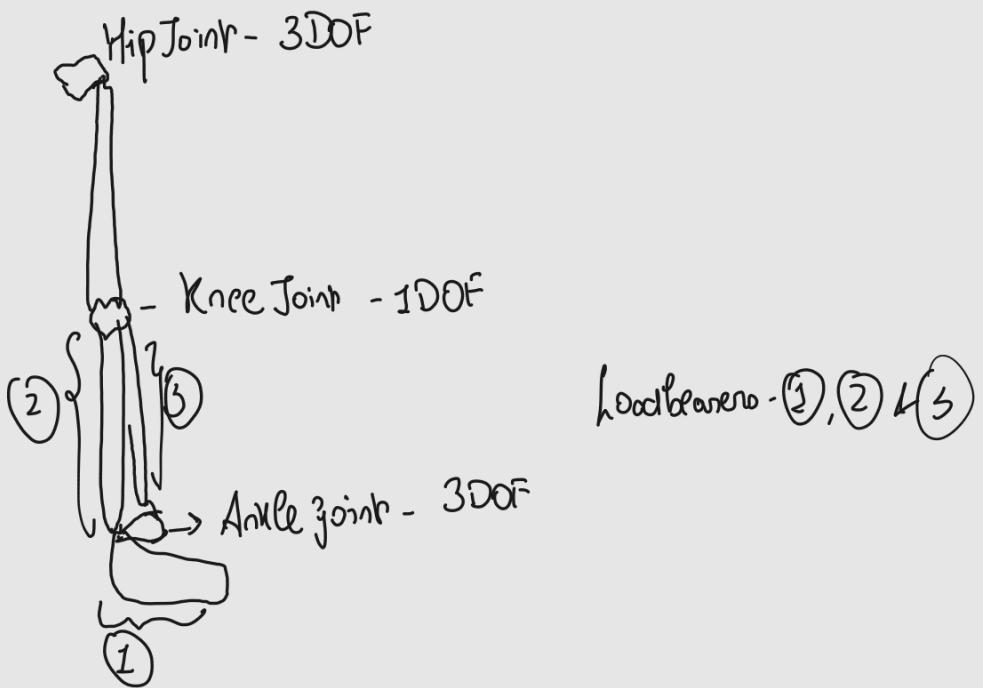

# Ergonomics

- 1) Joint mechanisms
- 2) Dof of each part  
(Knee, thigh, Ankle?)
- 3) Activation mechanism
- 4) Load capacity Parameters
  - 5) limits (mechanical)
- 6) Battery capacity.
- 7) Weight support distribution.

Probable End material :-

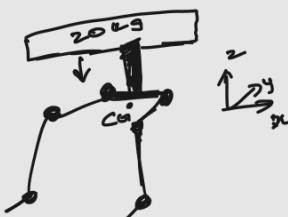

$$f = k_n$$

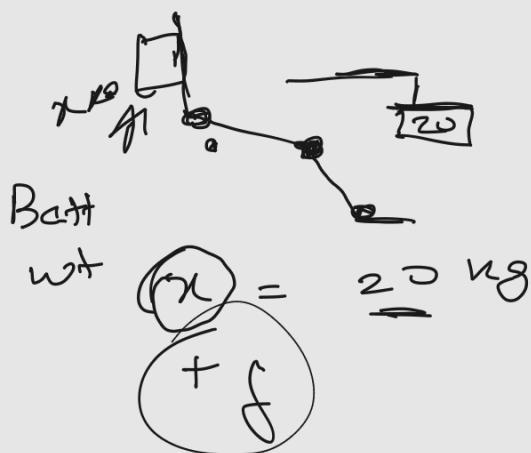

### Actuation Mechanism

Hydraulic      Servo Motor

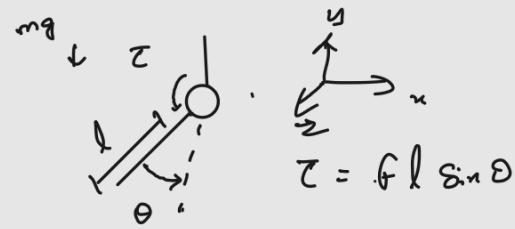

### Assumptions:

- 1) Box / weight always lifted parallel to the body and centred w.r.t body.
- 2) C.G located at hips
- 3)

Consideration of force in one joint:

$m$  - weight of obj

$l$  - length of the link

$e$  - exoskeleton weight

When lifting the weight

$$F = m(a)$$

$$F = \alpha(g)$$

$$F = \alpha g$$

$$\tau = l \cdot F \sin \theta$$

$$= l \cdot \alpha(g) \sin(\theta)$$

$$\tau = l \cdot \alpha(g) \sin(\theta)$$

$$\tau = l \cdot \alpha(g) + e'$$

$$\tau = g \alpha(l)$$

$$= 10 \text{ N/s} \times 20 \text{ s}$$

$$\sin \theta \begin{cases} 1 \\ -1 \end{cases}$$

range-

max  $\sin \theta$  is  
1

So when  $\sin \theta$

is 1 the

torque will

be max

with  $e$  [exoskeleton]

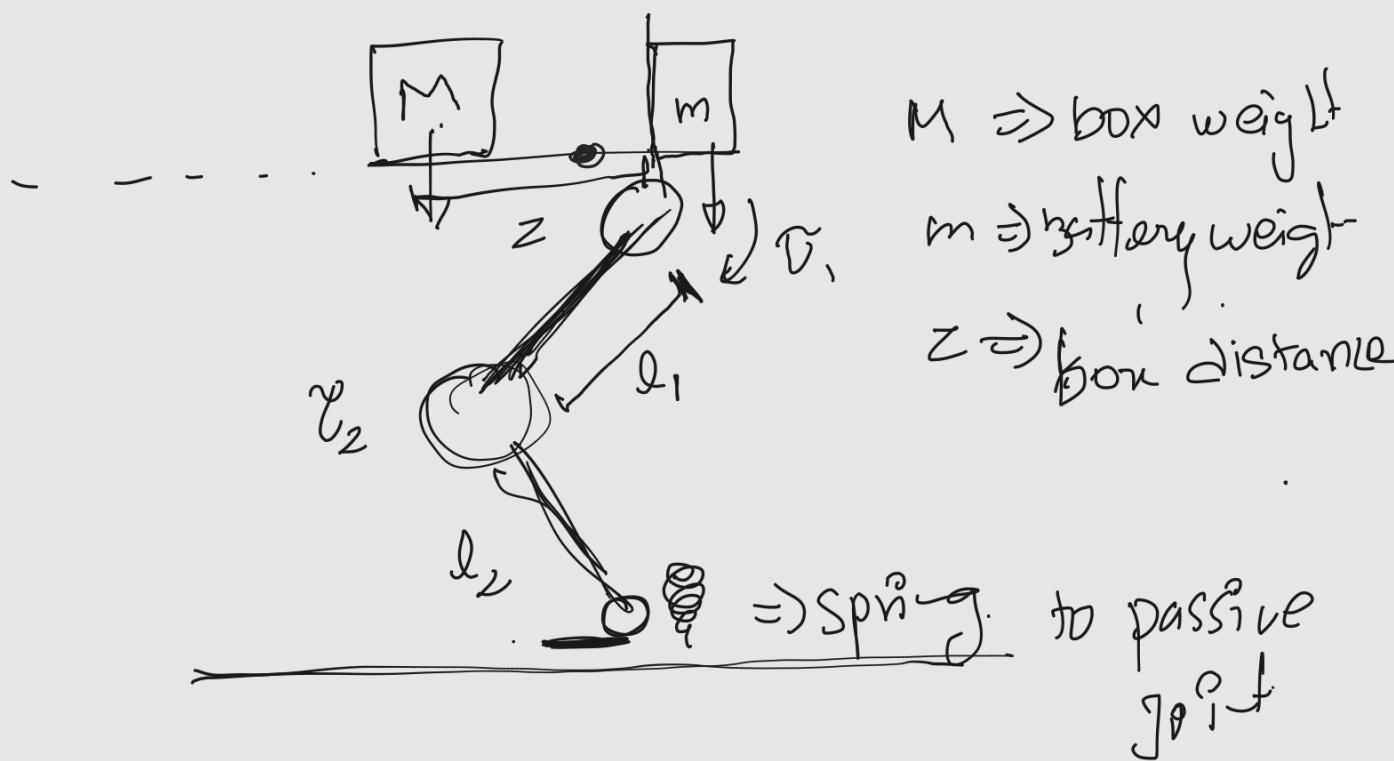

$$\tau = l \cdot (F + E) \sin \theta$$

$$= l \cdot (\alpha + e) g \sin \theta$$

$$\tau_{\max} = l \cdot (\alpha + e) g$$

# Exo Skeleton System

side view

$\tau_1 \Rightarrow$  hip joint torque

$\tau_2 \Rightarrow$  knee joint torque

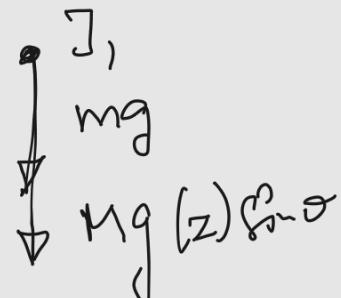

$$\text{on } \tau_1 \Rightarrow (Mg)(z) \sin \theta$$

$$\text{on } \tau_1 \Rightarrow mg$$

$$\begin{aligned} \tau_1 &= (Mg)(z) \sin \theta \\ &\quad + mg(z) \sin \theta \end{aligned}$$

$$\tau_2 = (mg)(z) \sin \theta$$

Free body  
 $J_1$

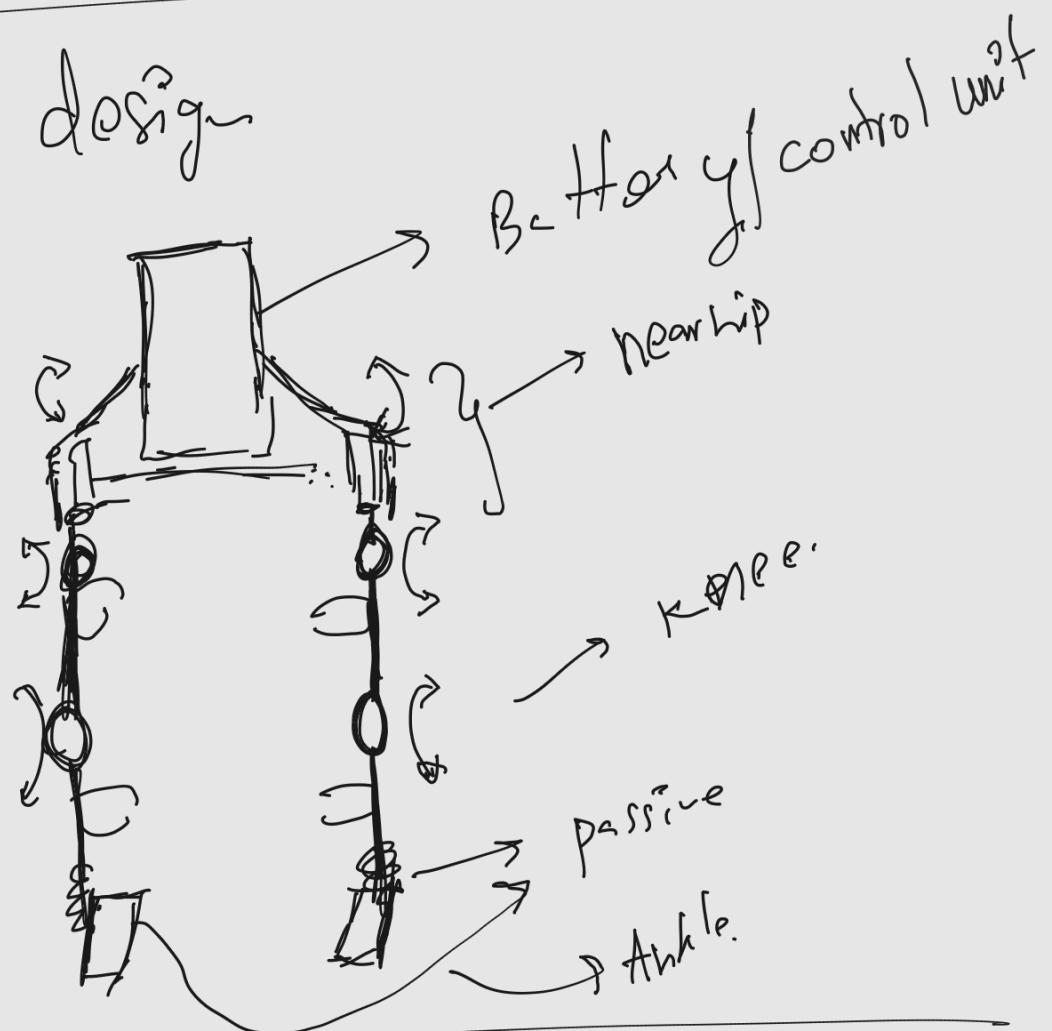

$$P_2 = \left[ (Mg(z) \sin\theta + mg) + Eg \right] l, \sin\theta$$

Force of weight

$\downarrow$   
Exoskeleton weight

Exoskeleton design

$$T_{body} = W \cdot d \sin\theta$$

blocks  $\rightarrow$  up to complete design

- \* correct torque calc
- \* (gear L & Body. weight)
- \* (winding up)
- \* Motor selection
- \* control logic
- \* Overall design

$z \rightarrow$  Horizontal dist from hip joint to box (m)

$z' \rightarrow$  Vertical distance from hip joint to com of battery

Hip joint torque ( $T_1$ )

$$T_{\text{box}} = M \cdot g \cdot z (\sin \theta) \quad (\text{Torque due to box's weight})$$

$$T_{\text{battery}} = m \cdot g \cdot z' \cdot \sin \theta \quad (\text{Torque due to battery's weight})$$

$$T_{\text{c}_0} = C \cdot l_{\text{hip}}/2$$
  
$$= T_1 + (M \cdot z + m \cdot z') g \sin \theta + C \frac{l_{\text{hip}}}{2}$$

Assumption: C is supposed to act at mid point of link below

hip & knee joint

Knee Joint Torque ( $T_2$ )

$$T_{\text{box}} = M \cdot g \cdot l_k \sin \theta$$

$l_{\text{hip}} \rightarrow$  length of  
link from hip joint to  
knee joint

$l_k \rightarrow$  length of knee  
joint to ankle

$$T_{\text{c}_0} = C \cdot l_{\text{knee}}/2 \quad \left. \begin{array}{l} \text{by assuming the weight} \\ \text{of lower part of exoskeleton} \end{array} \right.$$

$$T_2 = M g \cdot l_k \sin \theta + C \frac{l_k}{2} \quad \left. \begin{array}{l} \text{is half the weight of} \\ \text{exoskeleton} \end{array} \right.$$

$$T_2 = M_g \cdot l_k \sin\theta + \frac{e}{4} l_k$$

$$T_2 = l_k \left( M_g \sin\theta + \frac{e}{4} \right)$$

for thigh  $l_k = 46 \text{ cm}$  (model A)

$$l_k = 40 \text{ cm}$$

$$T_1, \quad \theta = \{ -30, 50 \}$$

$$T_2, \quad \theta = \{ 0, -40 \}$$

$$C_2 = l_k \left( Mg \sin \theta + \frac{e}{4} \right)$$

$$= 0.40 \left( 20 \times 9.81 \sin \theta + 2.5 \right)$$

$\theta = \{0^\circ, -40^\circ\}$

$$C_2 = -123.063 N_m \quad \left. \begin{array}{l} \theta = -40^\circ \\ \theta = 0^\circ \end{array} \right.$$

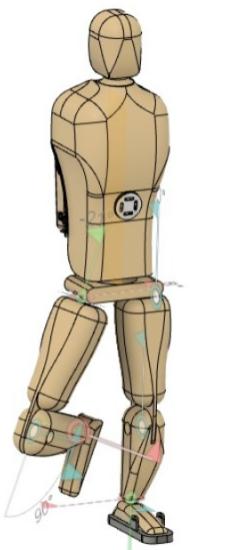

$$P_2 = 1017.51 \quad \left. \begin{array}{l} 50 \\ 30 \end{array} \right\} eg + Mg(z) \sin \theta + mg + Wg$$

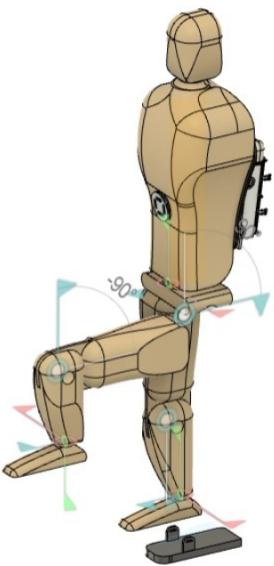

$$M(z) \sin \theta +$$

$$\ast (20(0.76) \sin \theta + 10 + 4 + 80)g$$

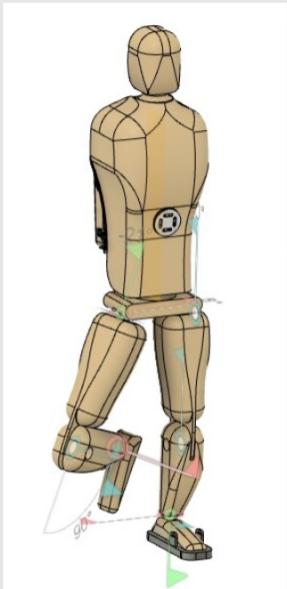

$$(20(0.76)^{0.64} + 10 + 4 + 80)g.$$

Model of a Human Body with a height of approximately 185 cm, has been created and the required joints have been made.

To aid with the ergonomic calculations the knee and thigh joints have been constrained to assemble actual human motion.

In all appropriate places, ball joints have been used.

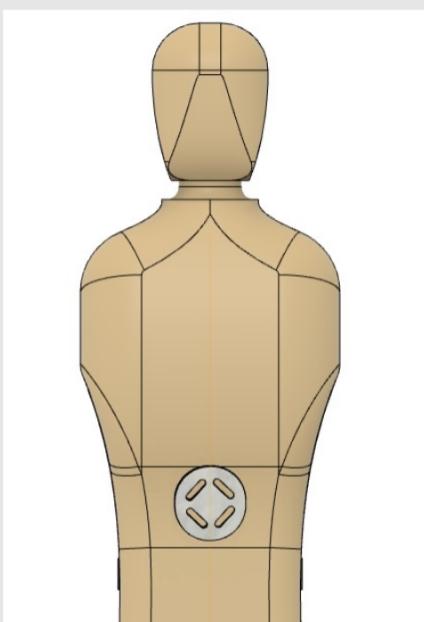

using 2, 1800 mAh 22.2V Li-Po batteries, which can be extended to 3-4 batteries to run for 8 hours.

We are planning to use Brushed 12V DC Motors in conjunction with Stepdown converters.

For the release mechanism of the belts that bind the torso part of exoskeleton to the body, two discs joined by a ball bearing are used.

The discs have 4 slots in them to lock in the respective belts. The top disc is rotated by the user to misalign the slots to securely lock the belt in place.

We are planning to use Harmonic Gearbox . that The reason is that ehrn compared to traditional gearboxes like cycloidal gears, it has high precision and almost little to no backlash , which is crucial in this context .

Specification

linear actuators :

- LA 23

- 6 spindle pitch

- 1500 N

## Hip joint Torques

$$90^\circ - 30^\circ \quad C_1 = -34.08 \text{ Nm}$$

$$0^\circ - 50^\circ \quad C_2 = 136.80 \text{ Nm}$$

$$C_1 = M.g.z \sin\theta + C_0 \frac{l_{hip}}{2}$$

$$\text{Knee joint torque} \quad + W_{upper}.g.D_{upper} \sin(\theta)$$

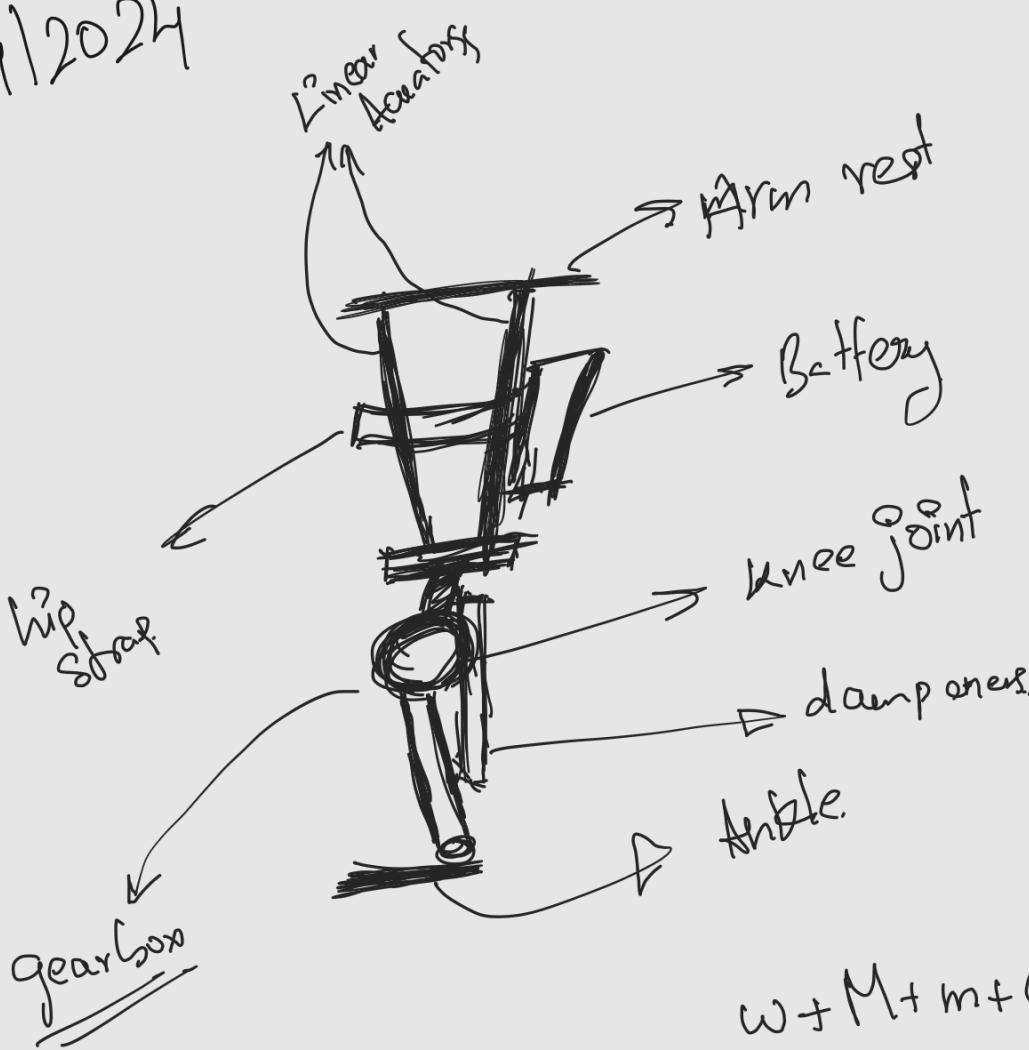

$$90^\circ - 43^\circ \rightarrow -93 \text{ Nm}$$

$$90^\circ \rightarrow 0 \text{ Nm}$$

$$C_2 = M.g.z \sin\theta + W_{upper}.D_{upper} \sin\theta$$

$$+ W_{lower}.g.D_{lower} \sin\theta$$

17/04/2024

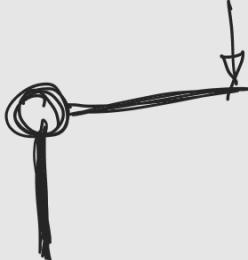

$$\omega + M + m + C$$

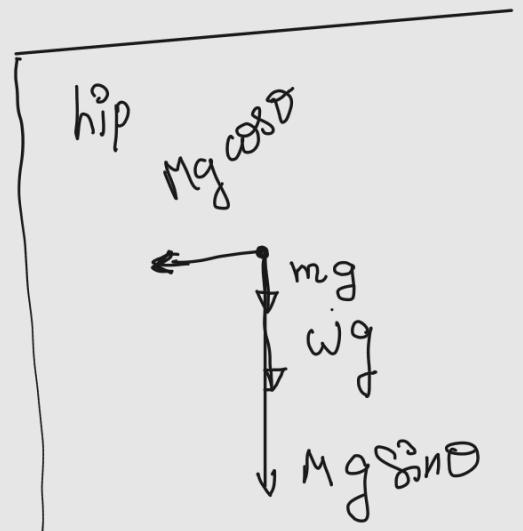

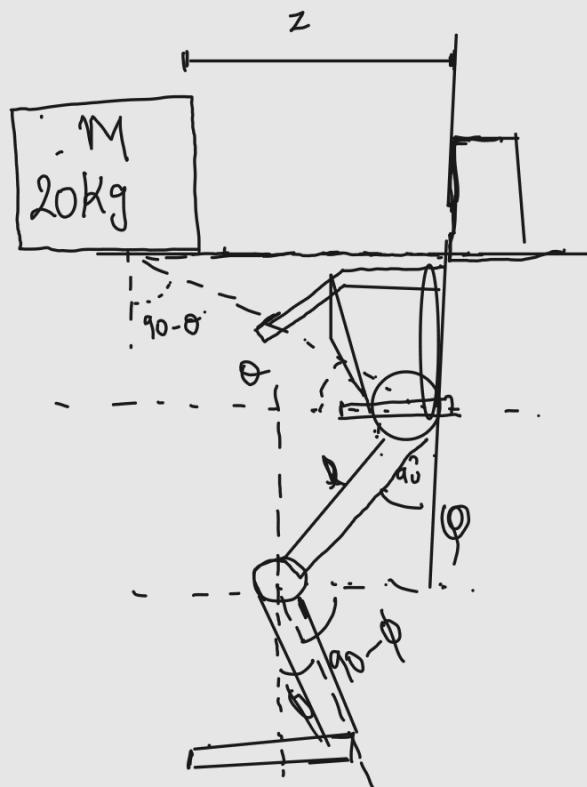

$$F_1 = 20 \times 9.8 = 196$$

$$F_2 = 80 \times 9.8 = 784$$

$$F_3 = 2 \times 9.8 = 20$$

$$F_4 = 10 \times 9.8 =$$

Descent  $\curvearrowright$  Ascent

knee.

M - Weight of the box

m - weight of battery pack

w. weight of human body

Z → Horizontal distance from hip joint to box

$Z'$  → Vertical distance from hip joint to COM of battery

e → Weight of exoskeleton

Assumptions

① The weight of exoskeleton is evenly distributed

② The weight of lower part of exoskeleton (below knee) is half of the entire weight.

# Hip Joint Torque ( $\tau_1$ )

$$\begin{aligned}\tau_{box} &= M \cdot g \cdot z \cdot \sin(90 - \theta) + M \cdot g \cdot l_{hip} \sin \theta \\ &= M \cdot g \cdot z \cos \theta + M \cdot g \cdot l_{hip} \sin \theta\end{aligned}$$

$$\tau_C = C \cdot g \cdot \left( \frac{l_{hip}}{2} \sin(\theta) \right)$$

$$\tau_1 = \tau_{box} + \tau_{knee} + \tau_C = M \cdot g (z \cos \theta + l_{hip} \sin \theta) + C \cdot g \left( \frac{l_{hip}}{2} \sin(\theta) \right)$$

For knee joints  $-30^\circ \leq \theta \leq 50^\circ$

$$z' = 0.35 \text{ m}$$

$$z = 0.76 \text{ m}$$

$$l_h = 0.46 \text{ m}$$

$$M = 20 \text{ kg}$$

$$m = 4 \text{ kg}$$

$$C = 20 \text{ kg}$$

$$\theta = 50^\circ \text{ (Descent)}$$

$$\tau_1 = 98.84 + 0.35 + 34.56 = 130.75 \text{ Nm}$$

$$\theta = -30^\circ \text{ (Ascent)}$$

$$\tau_1 = 64.56 + (-0.23) + (-22.56) \Rightarrow 41.77 \text{ Nm}$$

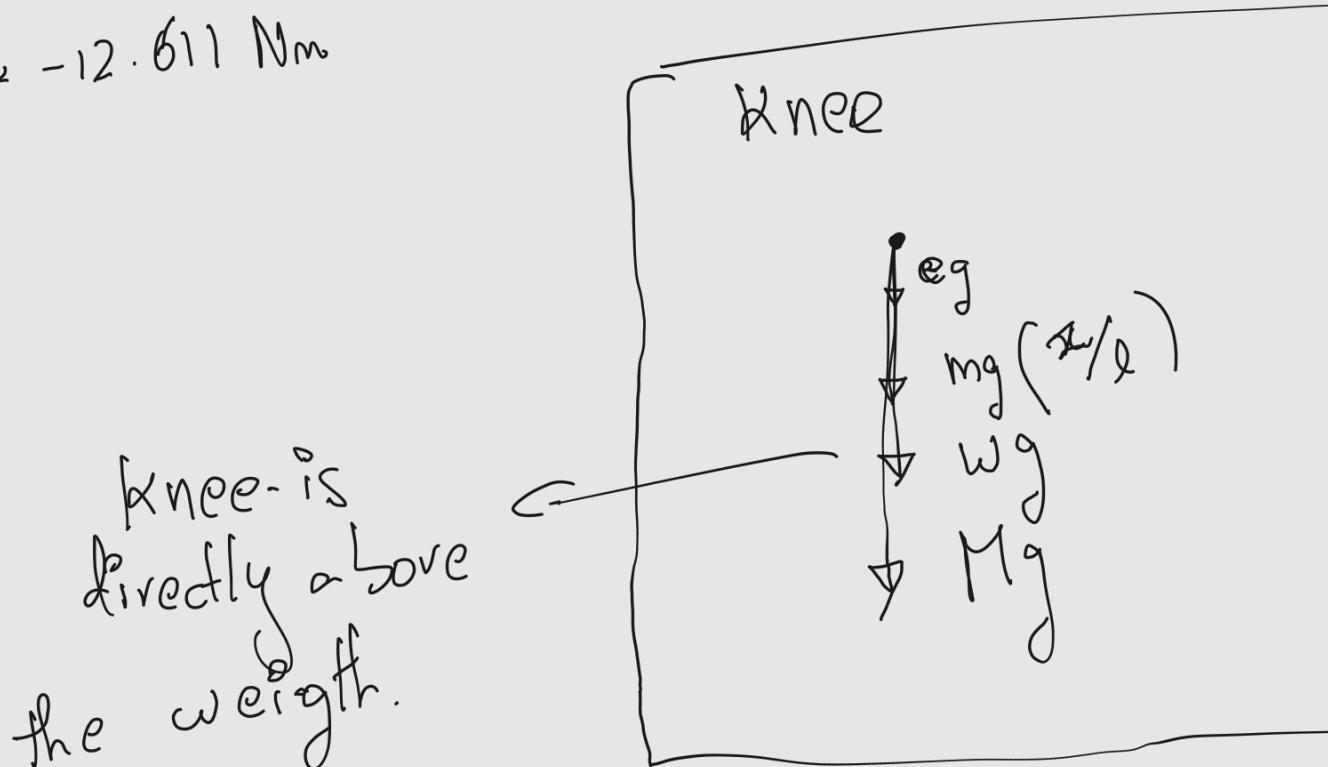

## Knee Joint Torque ( $T_2$ )

$T$  influenced by exoskeleton below the knee  $\rightarrow$  During descent

$$T_2 = \frac{C}{2} \cdot g \cdot \left( \frac{l_{knee}}{2} \sin(\theta) \right)$$

$$-40^\circ \leq \theta \leq 0^\circ$$

$$T_2 = 12.611 \text{ Nm}$$

Since we have to limit the weight using lithium is not feasible, hence Lipo is more of a better solution, hence

for running the entire setup, the batteries used for the system is 4 6s Lipo batteries with 10Ah capacity and a discharge rate of 35C.

Total power consumption:

→ Each linear actuators consume 7.4A at 12V.

$$\therefore P = V \times I$$

$$P = 12 \times 7.4$$

$$= 88.8 \text{ Watts}$$

for total of 8 actuators:

$$P = 8 \times 88.8$$

$$P = 710.4 \text{ watts}$$

Battery configuration & Total capacity:

$$\text{Total capacity} = 4 \times 10000$$

$$= 40 \text{ Ah}$$

Energy Availability of Battery:

$$E = V \times \text{capacity}$$

$$E = 22.2 \times 40$$

$$= 888 \text{ Wh}$$

Effective energy =

$$888 \text{ Wh} \times 0.95 = 843.6 \text{ Wh}$$

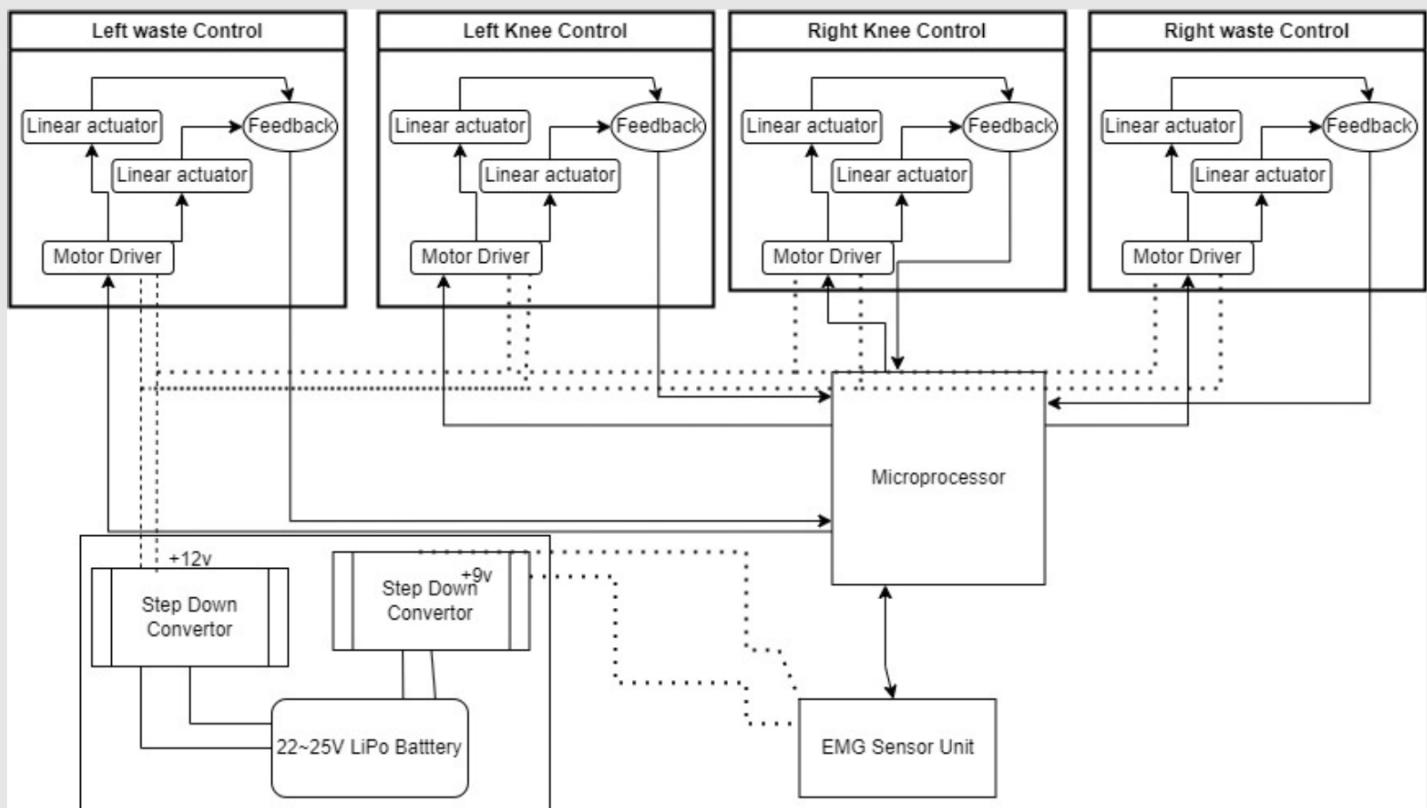

Expected Runtime:

$$R = \frac{\text{Effective Energy}}{\text{Total Power}}$$

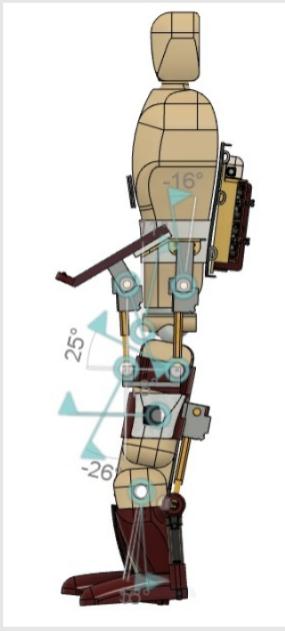

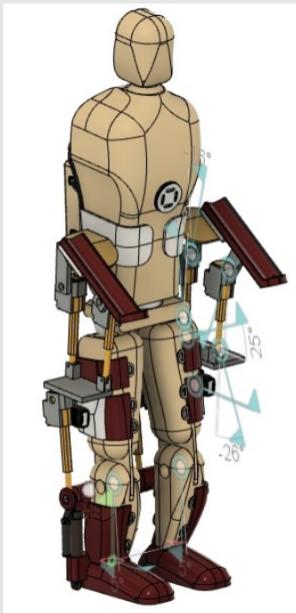

$$= \frac{843.6 \text{ Wh}}{710.4 \text{ W}}$$

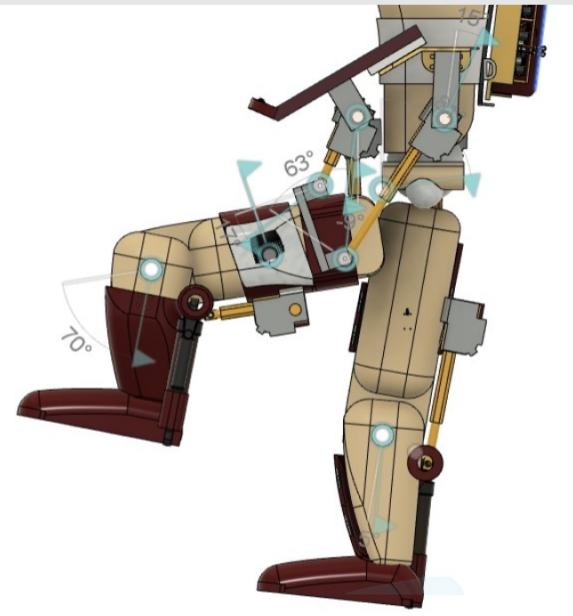

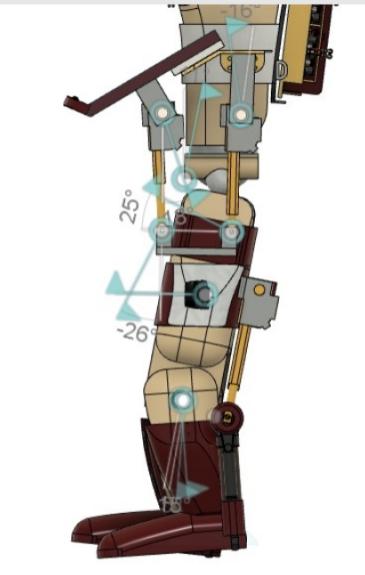

$$= 1.188 \text{ h}$$

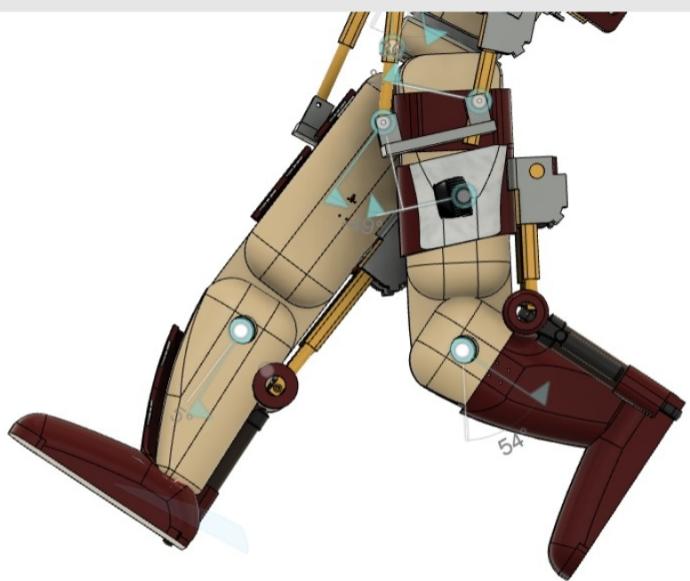

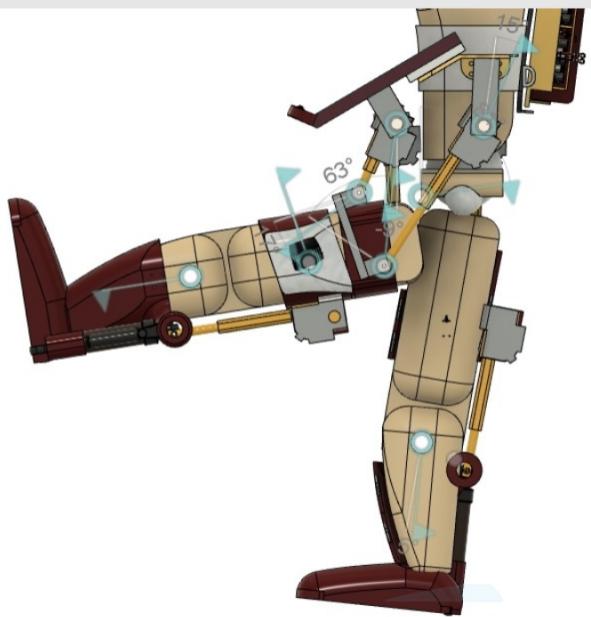

# Schematic diagram of the Exoskeleton and the components.

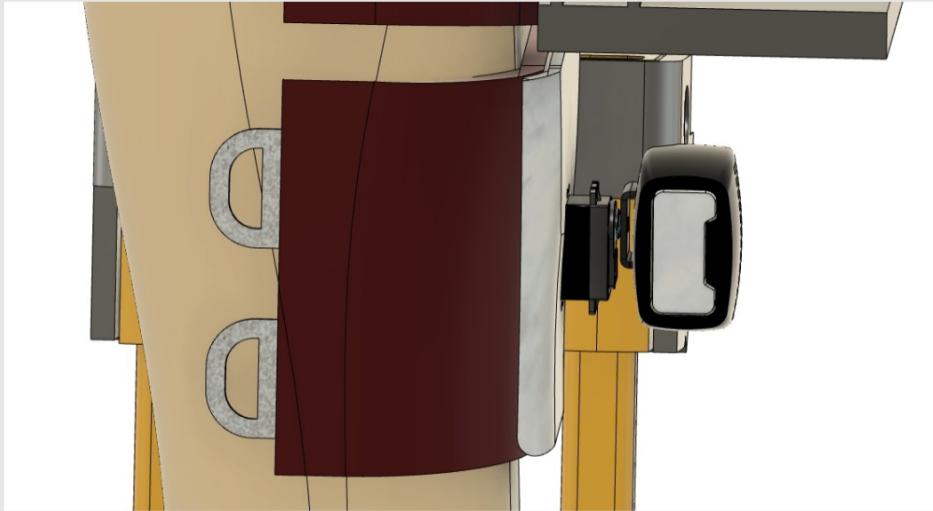

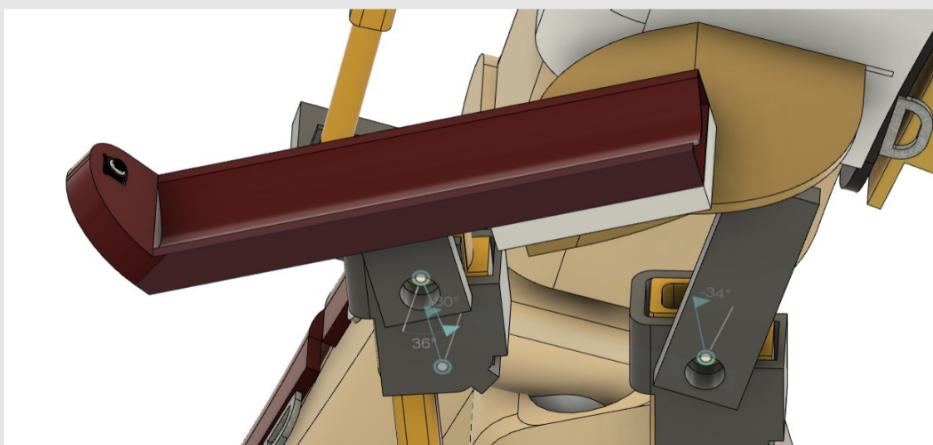

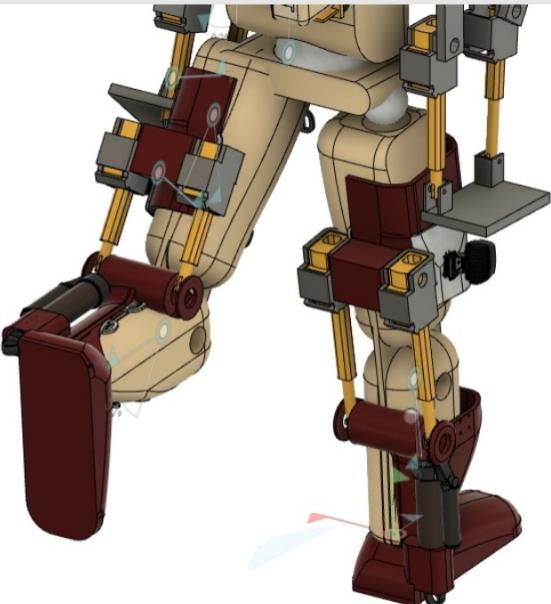

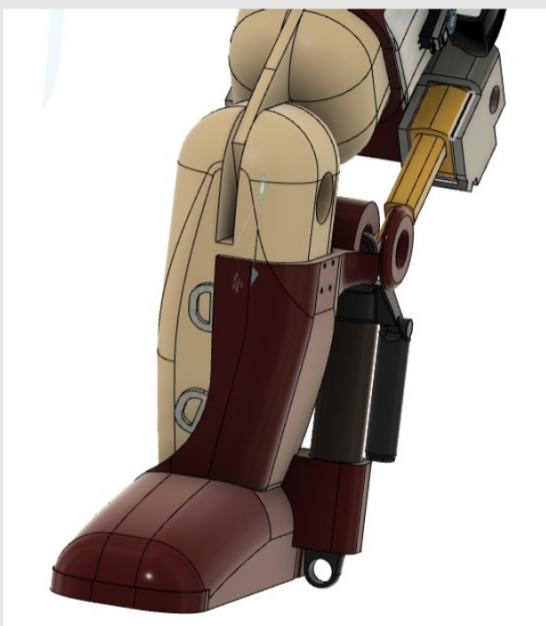

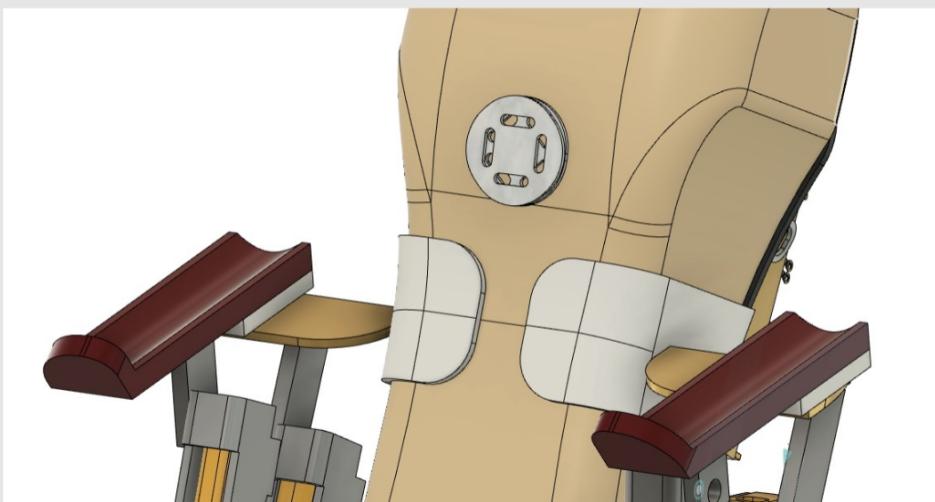

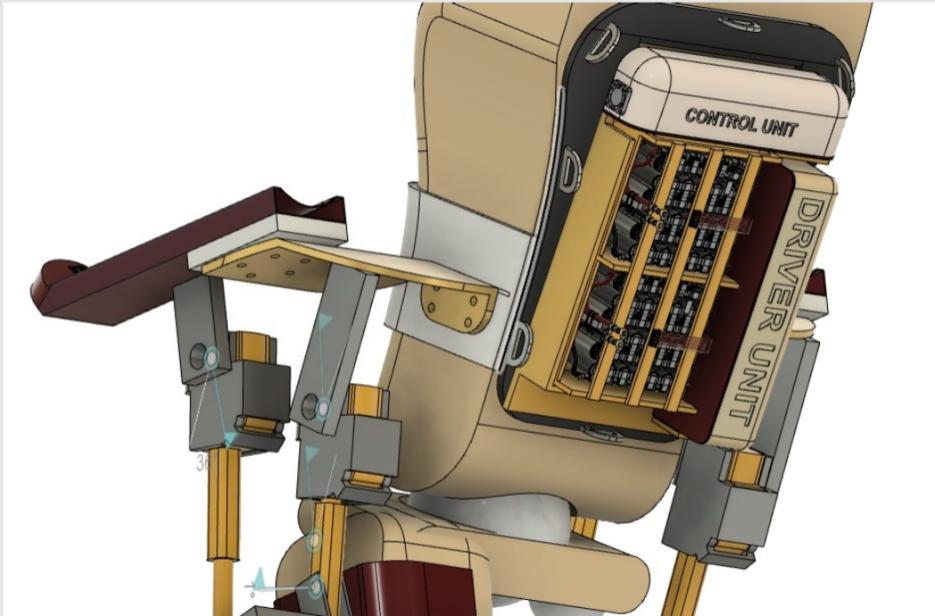

- \* LINAK LA23 Linear Actuators are being used
- \* 300W 10A DC-DC Stepdown Buck converters
- \* SmartAler DC motor Drivers.
- ~~\* Raspberry PI S.~~

This is our lower exoskeleton desgin.

The system consist of 8 Linear Acutators without any gearbox system.

it supports humans weight upto 80kgs and the person in the exoskeleton can lift upto 20kgs.

The unique design has hand holder stand where the user can place their hand while moving.

hip joint is controlled via totally 4 linear actuators, 2 per each joint.

the forward facing actuator will pull the thigh while we lift the leg and back face actuator will push the thigh. the same thing happens vice-versa.

the two linear actuators are connected below knee . While we knee joint is bent , the actuators will pull on the shoes .

The Knee joint has a limit of -40 to 0 and the hip joint has a limit of -30 to 50 (in degrees)

The ankle is connected to a dampening rod , which will transfer the weight from the joints smoothly into the ground .

The battery pack and the arm holder are connected to waist using a belt , from where the linear actuators are used to connect the torso to thigh

The exoskeleton weight after fitting all the motors is roughly estimated to be around 20kg - 25 kg . It is a very modular design and does not have any gearbox systems

Walking mechanism - The linear actuators allowed exoskeleton to move in various different directions and allowing more degrees of freedom.Due to high torque capacity and faster moving speed this mechanism is perfectly suitable for longer distances while carrying a load

As a additional feature we have added light systems near the thigh regions. The light systems are similar to fog lights found in vehicles .It can be useful while manuevering different terrains.

We have also added joystick control for this light systems in order to be able to tilt the light system in different angles . We have placed this joystick in the thumb area of armrest to enable the users to efficiently use this .We chose the design with armrest because we can add a lot of toher new features in the future as further improvements .

The half boot design features a cutout towards the right hand side of the boot to slide in and out the foot with ease , with adequate straps to prevent loosening . The boot also houses a dampener that extends when a load is lifted and when the sole is flat on the ground again, the dampening motion smoothens the returing motion .
